

Amendments to the Claims:

This listing of claims will replace all prior versions, and listings, of claims in the application:

Listing of Claims:

Claim 1 (original): A system for detecting transverse cracks in rail head on railway track comprising:

a transporter on the railway track, said transporter moving the system along the railway track,

a toroidal-shaped DC magnet mounted to the transporter with its opposing pole ends inwardly directed towards each other and aligned over the rail head,

an inductive coupling between each of the poles and the rail head to magnetically saturate the rail head, the inductive coupling slideably engaging the rail head,

at least one low frequency eddy current probe, centrally located between the poles of the toroidal-shaped DC magnet, for sensing said transverse cracks in the rail head,

protective material on the low frequency eddy current probe,

a carriage mounted to the transporter forcing said low frequency eddy current probe against said rail head, the protective material abutting the rail head when the transporter moves on the railway track thereby protecting the low frequency eddy current probe from damage.

Claim 2 (currently amended): The system of claim 1 further comprising:

one ~~or~~ of a plurality of supports on said carriage engaging the rail head for controlling lift-off of the low frequency eddy current probe from the rail head.

Claim 3 (currently amended): The system of claim 2 wherein said ~~one of~~ a plurality of supports are wheels.

Claim 4 (original): The system of claim 1 wherein the toroidal-shaped DC magnet has four layers of windings extending down towards the opposing ends.

Claim 5 (original): The system of claim 1 wherein the inductive coupling comprises a plurality of carbon steel bristles mounted to each of the pole ends.

Claim 6 (original): The system of claim 1 wherein the low frequency eddy current probe is an air core coil.

Claim 7 (currently amended): The system of claim 1 wherein the protective material is ~~TEFLON~~ polytetrafluoroethylene.

Claim 8 (original): The system of claim 1 wherein the carriage comprises two spring-loaded supports.

Claim 9 (original): The system of claim 1 wherein the plurality of wheels is four.

Claim 10 (currently amended): The system of claim 1 wherein the carriage ~~orients~~ locates the low frequency eddy current probe off the center of the rail.

Claim 11 (previously amended): A system for detecting transverse cracks in rail head on railway track comprising:

- a transporter on the railway track, said transporter moving the system along the railway track,

- a toroidal-shaped DC magnet mounted to the transporter with its opposing pole ends inwardly directed towards each other and aligned over the rail head,

- an inductive coupling between each of the poles and the rail head to magnetically saturate the rail head, the inductive coupling slideably engaging the rail head,

- at least one low frequency eddy current probe, centrally located between the poles of the toroidal-shaped DC magnet, for sensing said transverse cracks in the rail head,

- protective material on the low frequency eddy current probe,

- a separate sensor near said low frequency eddy current probe for sensing non-relevant indications in the rail head, said separate sensor held a predetermined distance above said rail head,

said system rejecting a sensed transverse crack when the separate sensor senses a non-relevant indication,

a carriage mounted to the transporter forcing said low frequency eddy current probe against said rail head, the protective material abutting the rail head when the transporter moves on the railway track thereby protecting the low frequency eddy current probe from damage.

Claim 12 (original): The system of claim 11 wherein the separate sensor is a Hall element sensor.

Claim 13 (original): The system of claim 1 wherein the at least one probe is one probe, the aforesaid one probe centered over the centerline of the rail head.

Claim 14 (currently amended): The system of claim 1 wherein the at least one probe is a plurality of probes, each of the aforesaid plurality of probes located across the rail head.

Claim 15 (canceled)

Claim 16 (original): A system for detecting transverse cracks in rail head on railway track comprising:

a transporter on the railway track, said transporter moving the system along the railway track,

a DC magnet mounted to the transporter with its opposing pole ends aligned over the rail head,

an inductive coupling between each of the poles and the rail head to magnetically saturate the rail head, the inductive coupling slideably engaging the rail head,

at least one low frequency eddy current probe, centrally located between the poles of the DC magnet and over said rail head, for sensing said transverse cracks in the rail head,

a separate sensor near said low frequency eddy current probe for sensing non-relevant indications in the rail head, said separate sensor held a predetermined distance above said rail head,

said system rejecting a sensed transverse crack from the low frequency eddy current probe in an area of the rail head when the separate sensor senses a non-relevant indication at said area.

Claim 17 (canceled)

Claim 18 (previously amended): A method for detecting transverse cracks in rail head of a rail comprising:

moving a transporter on the rail,

generating a saturated magnetic field into and across the rail head with a DC saturation magnet mounted to the transporter a predetermined distance above the rail head while the transporter is moving, the saturation magnet having a toroidal-shape with opposing pole ends inwardly directed towards each other over the rail head,

inductively coupling the opposing pole ends of the DC saturation magnet with the rail head,

detecting transverse cracks in the rail head with a low frequency eddy current probe mounted centrally between the opposing pole ends of the DC saturation magnetic and over the rail head,

applying a force to the low frequency eddy current probe against the rail head as the transporter moves on the rail,

controlling lift-off of the low frequency eddy current probe from the rail head as the transporter moves on the rail.

Claim 19 (previously amended): A method for detecting transverse cracks in rail head of a rail comprising:

moving a transporter on the rail,

generating a saturated magnetic field into and across the rail head with a DC saturation magnet mounted to the transporter a predetermined distance above the rail head

while the transporter is moving, the saturation magnet having a toroidal-shape with opposing pole ends inwardly directed towards each other over the rail head,

inductively coupling the opposing pole ends of the DC saturation magnet with the rail head,

detecting transverse cracks in the rail head with a low frequency eddy current probe mounted centrally between the opposing pole ends of the DC saturation magnetic and over the rail head,

applying a force to the low frequency eddy current probe against the rail head as the transporter moves on the rail,

controlling lift-off of the low frequency eddy current probe from the rail head as the transporter moves on the rail,

sensing non-relevant indications in the rail head with at least one separate sensor,

rejecting a detected transverse crack by the low frequency eddy current probe when it corresponds to a sensed non-relevant indication by the at least one separate sensor.

Claim 20 (original): A method for detecting a transverse crack in rail head of a rail comprising:

moving a transporter on the rail,

generating a saturation magnetic field into and across the rail head with a DC saturation magnet mounted to the transporter a predetermined distance above the rail head while the transporter is moving,

inductively coupling the opposing pole ends of the DC saturation magnet with the rail head,

detecting a possible transverse crack in an area of the rail head with a low frequency eddy current probe mounted centrally between the opposing pole ends of the DC saturation magnetic and over said area of the rail head,

sensing a non-relevant indication in said area of the rail head with at least one separate sensor,

rejecting said possible detected transverse crack by the low frequency eddy current probe only when said a non-relevant indication is sensed by the at least one separate sensor for said area.
